# Modification of the double direction approach for solving systems of nonlinear equations with application to Chandrasekhar's Integral equation 

A.I. Kiri, M.Y. Waziri and A.S. Halilu*

#### Abstract

This study aims to present an accelerated derivative-free method for solving systems of nonlinear equations using a double direction approach. The approach approximates the Jacobian using a suitably formed diagonal matrix by applying the acceleration parameter. Moreover, a norm descent line search is employed in the scheme to compute the optimal step length. Under the primary conditions, the proposed method's global convergence is proved. Numerical results are recorded in this paper using a set of large-scale test problems. Moreover, the new method is successfully used to address the problem of Chandrasekhar's integral equation problem appearing in radiative heat transfer. This method outperforms the existing Newton and inexact double step length methods.

[^0]
## 1 Introduction

Scientists are interested in nonlinear problems because most engineering, biology, mathematics, physics, and other science problems are naturally nonlinear. The standard nonlinear equation system is represented by

$$
\begin{equation*}
F(x)=0 \tag{1}
\end{equation*}
$$

where $F: \mathbb{R}^{n} \rightarrow \mathbb{R}^{n}$ is a nonlinear map. The space $\mathbb{R}^{n}$ denotes the $n$ dimensional real space, $\|\cdot\|$ is the Euclidean norm, and $F_{k}=F\left(x_{k}\right)$ is used throughout this paper. Further applications of problem (1) can be found in chemical equilibrium systems [16] and signal and image processing [25]. The Chandrasekhar H-equation that arises in the theory of radioactive heat transfer is a nonlinear integral equation that can be discretized into nonlinear equations [20]. Iterative methods for solving these problems include the Newton and quasi-Newton methods [4, 21, 26, 14], Levenberg-Marquardt methods $[15,13,12]$, matrix-free methods [17, 1, 8], and tensor methods [2]. Typically, the iterative formula for solving these methods is given by

$$
\begin{equation*}
x_{k+1}=x_{k}+\alpha_{k} d_{k}, \quad k=0,1, \ldots, \tag{2}
\end{equation*}
$$

where $x_{k+1}$ represents a current iterate, $x_{k}$ is the previous iterate, $\alpha_{k}$ is a step length, and $d_{k}$ is the search direction can be calculated by solving system of linear equations as follows:

$$
\begin{equation*}
F_{k}+F_{k}^{\prime} d_{k}=0 \tag{3}
\end{equation*}
$$

where $F_{k}^{\prime}$ is the Jacobian matrix of $F_{k}$ at $x_{k}$. One of the most important requirements of the line search is to reduce the function values sufficiently [ 9,11 ], as shown below:

$$
\begin{equation*}
\left\|F_{k+1}\right\| \leq\left\|F_{k}\right\| \tag{4}
\end{equation*}
$$

Irrespective of how appealing the Newton and quasi-Newton approaches are, the Jacobian matrix or its approximation can be calculated at each iteration, making them unsuitable for solving large-scale problems. Due to the drawbacks of these methods, the double direction technique has been proposed [6], with the following iterate:

$$
\begin{equation*}
x_{k+1}=x_{k}+\alpha_{k} d_{k}+\alpha_{k}^{2} b_{k} \tag{5}
\end{equation*}
$$

where $d_{k}$ and $b_{k}$ are search directions, respectively.
Suppose that $f$ is a merit function defined by

$$
\begin{equation*}
f(x)=\frac{1}{2}\|F(x)\|^{2} \tag{6}
\end{equation*}
$$

Then problem (1) is analogous to the unconstrained optimization problem described below:

$$
\begin{equation*}
\min f(x), \quad x \in \mathbb{R}^{n} \tag{7}
\end{equation*}
$$

where $f: \mathbb{R}^{n} \rightarrow \mathbb{R}$, and condition (4) is equivalent to

$$
\begin{equation*}
f\left(x_{k}+\alpha_{k} d_{k}\right) \leq f\left(x_{k}\right) \tag{8}
\end{equation*}
$$

The iterative method generating the sequence $\left\{x_{k}\right\}$ that satisfies (4) is called the norm descent method [9]. If $d_{k}$ is a descent direction of $f$ at $x_{k}$, then condition (8) holds for all $\alpha_{k}>0$ small enough. The Newton method (NM) with line search is norm descent. Nonetheless, $d_{k}$ might not be a descent direction of $f$ at $x_{k}$ for quasi-Newton methods, even if the approximation of the Jacobian matrix $B_{k}$ is positive definite and symmetric. Li and Fukushima [14] proposed an approximately norm-descent line search approach. However, the proposed method is not norm descent, but they established a global convergence theorem under the assumption that Jacobian is uniformly nonsingular.

The concept of the double direction approach was suggested by DuranovićMiličić [6] by using a multi-step iterative scheme and curve search to generate new iterates. However, in [7], another double direction algorithm was also presented to minimize nondifferentiable functions. Motivated by the work presented in [7], Petrović and Stanimirović [19] suggested a double direction model for solving unconstrained optimization problems. They used the acceleration parameter $\gamma_{k}$ to approximate the Hessian matrix, that is,

$$
\begin{equation*}
\nabla^{2} f\left(x_{k}\right) \approx \gamma_{k} I \tag{9}
\end{equation*}
$$

where $I$ is the identity matrix, and the sequence of iterates $\left\{x_{k}\right\}$ is generated using (5). The attractive feature of the scheme in [19] is that the two directions presented in their work are derivative-free. Therefore, it enables their method to solve large-scale problems. However, the literature is infrequent to study derivative-free double direction methods for solving nonlinear equations. Based upon the idea presented in [19], Halilu and Waziri used the scheme in (5) to propose a method for solving a system of nonlinear equations using a double direction approach. They used the acceleration parameter $\gamma_{k}>0$ in their work to approximate the Jacobian matrix, that is,

$$
\begin{equation*}
F_{k}^{\prime} \approx \gamma_{k} I \tag{10}
\end{equation*}
$$

where $I$ is an identity matrix and the acceleration parameter is derived as

$$
\begin{equation*}
\gamma_{k+1}=\frac{y_{k}^{T} y_{k}}{\left(\alpha_{k}+\alpha_{k}^{2} \gamma_{k}\right) y_{k}^{T} d_{k}} . \tag{11}
\end{equation*}
$$

The method's global convergent is proved by assuming that the Jacobian of $F$ is positive definite and bounded. The double direction scheme is justified
by the fact that scheme (5) contains two corrections. If one of the iterative corrections fails, then the system will be corrected by the second.

The implementation of double direction is additionally enhanced by Petrović [18], where the double step length scheme for the unconstrained optimization problem is presented as

$$
\begin{equation*}
x_{k+1}=x_{k}+\alpha_{k} d_{k}+\beta_{k} b_{k} \tag{12}
\end{equation*}
$$

where $\alpha_{k}$ and $\beta_{k}$ are two different step lengths. The numerical results indicated the approach is quite effective compared to the double direction method in [19]. The authors in [8] incorporated the concept in (12) and transformed the double step length method for solving (1) to improve the numerical results and global convergence properties of the double direction scheme. The numerical results exhibited that the method in [8] is more reasonable than the method in [10] because it converges faster. Furthermore, the method [8] is globally converged using the line search proposed in [14]. Motivated by the work in [8], Halilu and Waziri [11] presented an inexact double step length method for solving (1). The attractive feature of this method is that it has a double step length and a single direction that satisfies the decent properties independent of line search. Despite the good convergence properties of the method in [10], its numerical performance is defined as weaker. Therefore, motivated by this reason, we aim to develop a globally converged derivative-free method with a line search to solve a system of nonlinear equations without calculating the Jacobian matrix.

The research gap between the existing method and this article is described in Table 1 above. The table clearly shows that only the proposed method is derivative-free, matrix-free, double direction method, globally convergent, and can be applied to solve discretized Chandrasekhar's integral equation among the listed articles.

We now describe how the paper is structured. The proposed method's algorithm will be presented in section 2. Section 3 illustrates the convergence
results. Section 4 contains a list of numerical experiments and applications of the proposed method to Chandrasekhar's integral equation, which arises in radiative heat transfer. Section 5 concludes the paper.

## 2 Main result

In this section, we present the algorithm of our method. We suggest that the $d_{k}$ and $b_{k}$ in (5) are defined as follows:

$$
\begin{equation*}
d_{k}=-\gamma_{k}^{-1} F_{k} \tag{13}
\end{equation*}
$$

and

$$
\begin{equation*}
b_{k}=-F_{k} \tag{14}
\end{equation*}
$$

where $\gamma_{k}>0$ is an acceleration parameter. By substituting (13) and (14) into (5), we obtain

$$
\begin{equation*}
x_{k+1}=x_{k}-\left(\alpha_{k}+\alpha_{k}^{2} \gamma_{k}\right) \gamma_{k}^{-1} F_{k} \tag{15}
\end{equation*}
$$

The acceleration parameter can be obtained using Taylor's series expansion below:

$$
\begin{equation*}
F_{k+1} \approx F_{k}+F^{\prime}(\psi)\left(x_{k+1}-x_{k}\right) \tag{16}
\end{equation*}
$$

By multiplying (16) through by $\theta_{k}$, we have

$$
\begin{equation*}
\theta_{k} F_{k+1} \approx \theta_{k} F_{k}+\theta_{k} F^{\prime}(\psi)\left(\alpha_{k}+\alpha_{k}^{2} \gamma_{k}\right) d_{k} \tag{17}
\end{equation*}
$$

where $\theta_{k}>0$ and $\psi$ satisfies the conditions $\psi \in\left[x_{k}, x_{k+1}\right]$ and

$$
\begin{equation*}
\psi=x_{k}+\zeta\left(x_{k+1}-x_{k}\right), \quad 0 \leq \zeta \leq 1 \tag{18}
\end{equation*}
$$

Taking $\zeta=1$ in (18), obtain $\psi=x_{k+1}$.
We like to make Jacobian approximations via

$$
\begin{equation*}
\theta_{k} F^{\prime}(\psi) \approx \gamma_{k+1} I \tag{19}
\end{equation*}
$$

Using (17) and (19), it is easy to confirm that

$$
\begin{equation*}
\gamma_{k+1} s_{k}=\theta_{k} y_{k} \tag{20}
\end{equation*}
$$

where $s_{k}=\left(\alpha_{k}+\alpha_{k}^{2} \gamma_{k}\right) d_{k}, y_{k}=F_{k+1}-F_{k}$, and $\theta_{k}=\frac{s_{k}^{T} s_{k}}{y_{k}^{T} s_{k}}$ (see [24]).
The proposed acceleration parameter is defined by multiplying $y_{k}^{T}$ on both sides of (20)

$$
\begin{equation*}
\gamma_{k+1}=\frac{\left\|s_{k}\right\|^{2}\left\|y_{k}\right\|^{2}}{\left(\alpha_{k}+\alpha_{k}^{2} \gamma_{k}\right)^{2}\left(y_{k}^{T} d_{k}\right)^{2}} \tag{21}
\end{equation*}
$$

Our proposed scheme is given by equation (22) below based on (13) and (15):

$$
\begin{equation*}
x_{k+1}=x_{k}+\left(\alpha_{k}+\alpha_{k}^{2} \gamma_{k}\right) d_{k} \tag{22}
\end{equation*}
$$

```
Algorithm 1 Modification of the double direction approach (MDFDD)
Input: Given \(x_{0}, \gamma_{0}=1, \epsilon=10^{-5}, \phi_{1}>0, \phi_{2}>0\), and \(r \in(0,1)\), set \(k=0\).
Step 1: Compute \(F_{k}\).
Step 2: If \(\left\|F_{k}\right\| \leq \epsilon\), then stop; otherwise, proceed to Step 3.
Step 3: Calculate search direction \(d_{k}=-\gamma_{k}^{-1} F_{k}\).
Step 4: Set \(x_{k+1}=x_{k}+\left(\alpha_{k}+\alpha_{k}^{2} \gamma_{k}\right) d_{k}\), where \(\alpha_{k}=r^{a_{k}}\) with \(a_{k}\) being the
```

smallest nonnegative integer $a$ such that

$$
\begin{equation*}
f\left(x_{k}+\left(\alpha_{k}+\alpha_{k}^{2} \gamma_{k}\right) d_{k}\right)-f\left(x_{k}\right) \leq-\phi_{1}\left\|\alpha_{k} F_{k}\right\|^{2}-\phi_{2}\left\|\alpha_{k} d_{k}\right\|^{2}+\tau_{k} f\left(x_{k}\right) \tag{23}
\end{equation*}
$$

Let $\left\{\tau_{k}\right\}$ be a given positive sequence such that

$$
\begin{equation*}
\sum_{k=0}^{\infty} \tau_{k}<\tau<\infty \tag{24}
\end{equation*}
$$

Step 5: Compute $F_{k+1}$.
Step 6: Determine $\gamma_{k+1}=\frac{\left\|s_{k}\right\|^{2}\left\|y_{k}\right\|^{2}}{\left(\alpha_{k}+\alpha_{k}^{2} \gamma_{k}\right)^{2}\left(y_{k}^{T} d_{k}\right)^{2}}$.
Step 7: Consider $k=k+1$ and go to Step 2.

## 3 Convergence Analysis

We present how the proposed Algorithm 2 (MDFDD) converges globally in this section. Let us start by defining the level set

$$
\begin{equation*}
\Omega=\left\{x \mid\|F(x)\| \leq\left\|F\left(x_{0}\right)\right\|\right\} . \tag{25}
\end{equation*}
$$

However, we require the following assumptions:
Assumption 1. However, we state the following assumptions:

1. There exists $x^{*} \in \mathbb{R}^{n}$ such that $F\left(x^{*}\right)=0$.
2. $F$ is continuously differentiable in some neighborhood say $Q$ of $x^{*}$ containing $\Omega$.
3. The Jacobian of $F$ is bounded and positive definite on Q. That is, there exist positive constants $H>h>0$ such that

$$
\begin{equation*}
\left\|F^{\prime}(x)\right\| \leq H \quad \text { for all } x \in Q \tag{26}
\end{equation*}
$$

and

$$
\begin{equation*}
h\|d\|^{2} \leq d^{T} F^{\prime}(x) d \quad \text { for all } x \in Q, d \in \mathbb{R}^{n} \tag{27}
\end{equation*}
$$

Remark 1. We make the following remark:
Assumption 1 implies that there exist constants $H>h>0$ such that

$$
\begin{align*}
h\|d\| & \leq\left\|F^{\prime}(x) d\right\| \leq H\|d\| \quad \text { for all } x \in Q, d \in \mathbb{R}^{n}  \tag{28}\\
h\|x-y\| & \leq\|F(x)-F(y)\| \leq H\|x-y\| \quad \text { for all } x, y \in Q \tag{29}
\end{align*}
$$

Since $\gamma_{k} I$ approximates $F_{k}^{\prime}$ along $s_{k}$, the following assumption can be made.

Assumption 2. $\gamma_{k} I$ is a good approximation to $F_{k}^{\prime}$, that is,

$$
\begin{equation*}
\left\|\left(F_{k}^{\prime}-\gamma_{k} I\right) d_{k}\right\| \leq \varepsilon\left\|F_{k}\right\| \tag{30}
\end{equation*}
$$

where $\varepsilon \in(0,1)$ is a small quantity [26].
Lemma 1. Suppose that Assumption 2 holds, and let $\left\{x_{k}\right\}$ be generated by the MDFDD algorithm. Then $d_{k}$ is a sufficient descent direction for $f\left(x_{k}\right)$ at $x_{k}$, that is,

$$
\begin{equation*}
\nabla f\left(x_{k}\right)^{T} d_{k}<c\left\|F_{k}\right\|^{2}, \quad c>0 \tag{31}
\end{equation*}
$$

Proof. From (13), we have

$$
\begin{align*}
\nabla f\left(x_{k}\right)^{T} d_{k} & =F_{k}^{T} F_{k}^{\prime} d_{k} \\
& =F_{k}^{T}\left[\left(F_{k}^{\prime}-\gamma_{k} I\right) d_{k}-F_{k}\right]  \tag{32}\\
& =F_{k}^{T}\left(F_{k}^{\prime}-\gamma_{k} I\right) d_{k}-\left\|F_{k}\right\|^{2}
\end{align*}
$$

by the Cauchy-Schwarz inequality, we have

$$
\begin{align*}
\nabla f\left(x_{k}\right)^{T} d_{k} & \leq\left\|F_{k}\right\|\left\|\left(F_{k}^{\prime}-\gamma_{k} I\right) d_{k}\right\|-\left\|F\left(x_{k}\right)\right\|^{2} \\
& \leq-(1-\epsilon)\left\|F\left(x_{k}\right)\right\|^{2} . \tag{33}
\end{align*}
$$

This lemma is true for $\varepsilon \in(0,1)$.
We can conclude from Lemma 1 that the norm function $f\left(x_{k}\right)$ is a descent along $d_{k}$, which means that $\left\|F_{k+1}\right\| \leq\left\|F_{k}\right\|$ is true.

Lemma 2. Suppose that Assumption 1 holds, and let $\left\{x_{k}\right\}$ be generated by the MDFDD algorithm. Then $\left\{x_{k}\right\} \subset \Omega$.

Proof. From Lemma 1, we have $\left\|F_{k+1}\right\| \leq\left\|F_{k}\right\|$. Furthermore, for all $k$,

$$
\left\|F_{k+1}\right\| \leq\left\|F_{k}\right\| \leq\left\|F_{k-1}\right\| \leq \cdots \leq\left\|F_{0}\right\|
$$

This means that $\left\{x_{k}\right\} \subset \Omega$.

Lemma 3 (see [26]). Suppose that Assumption 1 holds, and let $\left\{x_{k}\right\}$ be generated by the MDFDD algorithm. Then there exists a constant $m>0$ such that for all $k$,

$$
\begin{equation*}
y_{k}^{T} s_{k} \geq h\left\|s_{k}\right\|^{2} \tag{34}
\end{equation*}
$$

Lemma 4. Suppose that Assumption 1 holds and that $\left\{x_{k}\right\}$ is generated by the MDFDD algorithm. Then

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|\alpha_{k} d_{k}\right\|=\lim _{k \rightarrow \infty}\left\|s_{k}\right\|=0 \tag{35}
\end{equation*}
$$

and

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|\alpha_{k} F_{k}\right\|=0 \tag{36}
\end{equation*}
$$

Proof. By (23) for all $k>0$

$$
\begin{align*}
\phi_{2}\left\|\alpha_{k} d_{k}\right\|^{2} & \leq \phi_{1}\left\|\alpha_{k} F_{k}\right\|^{2}+\phi_{2}\left\|\alpha_{k} d_{k}\right\|^{2} \\
& \leq\left\|F_{k}\right\|^{2}-\left\|F_{k+1}\right\|^{2}+\tau_{k}\left\|F_{k}\right\|^{2} . \tag{37}
\end{align*}
$$

By summing the above inequality, we have

$$
\begin{align*}
\phi_{2} \sum_{i=0}^{k}\left\|\alpha_{i} d_{i}\right\|^{2} & \leq \sum_{i=0}^{k}\left(\left\|F_{i}\right\|^{2}-\left\|F_{i+1}\right\|^{2}\right)+\sum_{i=0}^{k} \eta_{i}\left\|F_{i}\right\|^{2} \\
& =\left\|F_{0}\right\|^{2}-\left\|F_{k+1}\right\|^{2}+\sum_{i=0}^{k} \tau_{i}\left\|F_{i}\right\|^{2}  \tag{38}\\
& \leq\left\|F_{0}\right\|^{2}+\left\|F_{0}\right\|^{2} \sum_{i=0}^{k} \tau_{i} \\
& \leq\left\|F_{0}\right\|^{2}+\left\|F_{0}\right\|^{2} \sum_{i=0}^{\infty} \tau_{i}
\end{align*}
$$

From the level set and the fact that $\left\{\tau_{k}\right\}$ satisfies (24), then the series $\sum_{i=0}^{\infty}\left\|\alpha_{i} d_{i}\right\|^{2}$ converges. This implies (35). Using the same logic as above, but this time with $\phi_{1}\left\|\alpha_{k} F_{k}\right\|^{2}$ on the left, we obtain (36).

Lemma 5. Suppose that Assumption 1 holds, and let $\left\{x_{k}\right\}$ be generated by the MDFDD algorithm. Then there exists a constant $m_{1}>0$ such that for all $k>0$,

$$
\begin{equation*}
\left\|d_{k}\right\| \leq B \tag{39}
\end{equation*}
$$

Proof. From (13) and (21), we have

$$
\begin{align*}
\left\|d_{k}\right\| & =\left\|-\frac{\left(y_{k-1}^{T} s_{k-1}\right)^{2} F_{k}}{\left\|y_{k-1}\right\|^{2}\left\|s_{k-1}\right\|^{2}}\right\| \\
& \leq \frac{\left\|F_{k}\right\|\left\|s_{k-1}\right\|^{2}\left\|y_{k-1}\right\|^{2}}{\left\|s_{k-1}\right\|^{2}\left\|y_{k-1}\right\|^{2}}  \tag{40}\\
& \leq\left\|F_{0}\right\| .
\end{align*}
$$

Choosing $B=\left\|F_{0}\right\|$, we have (39).

Theorem 1. Suppose that Assumption 1 holds, and let $\left\{x_{k}\right\}$ be generated by the MDFDD algorithm. Assume further, for all $k>0$,

$$
\begin{equation*}
\alpha_{k} \geq \lambda \frac{\left|F_{k}^{T} d_{k}\right|}{\left\|d_{k}\right\|^{2}} \tag{41}
\end{equation*}
$$

where $\lambda$ is some positive constant. Then

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|F_{k}\right\|=0 \tag{42}
\end{equation*}
$$

Proof. From Lemma 5, we have (39). Also, from (35) and the boundedness of $\left\{\left\|d_{k}\right\|\right\}$, we have

$$
\begin{equation*}
\lim _{k \rightarrow \infty} \alpha_{k}\left\|d_{k}\right\|^{2}=0 \tag{43}
\end{equation*}
$$

From (41) and (43), we have

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left|F_{k}^{T} d_{k}\right|=0 \tag{44}
\end{equation*}
$$

Also, from (13), we have

$$
\begin{align*}
F_{k}^{T} d_{k} & =-\gamma_{k}^{-1}\left\|F_{k}\right\|^{2}  \tag{45}\\
\left\|F_{k}\right\|^{2} & =\left\|-F_{k}^{T} d_{k} \gamma_{k}\right\|  \tag{46}\\
& \leq\left|F_{k}^{T} d_{k} \| \gamma_{k}\right|
\end{align*}
$$

Since

$$
\gamma_{k}^{-1}=\frac{\left(y_{k-1}^{T} s_{k-1}\right)^{2}}{\left\|y_{k-1}\right\|^{2}\left\|s_{k-1}\right\|^{2}} \geq \frac{h^{2}\left\|s_{k-1}\right\|^{4}}{\left\|y_{k-1}\right\|^{2}\left\|s_{k-1}\right\|^{2}} \geq \frac{h^{2}\left\|s_{k-1}\right\|^{2}}{H^{2}\left\|s_{k-1}\right\|^{2}}=\frac{h^{2}}{H^{2}}
$$

then

$$
\left|\gamma_{k}^{-1}\right| \geq \frac{h^{2}}{H^{2}}
$$

Therefore from (46), we have

$$
\begin{equation*}
\left\|F_{k}\right\|^{2} \leq\left|F_{k}^{T} d_{k}\right|\left(\frac{H^{2}}{h^{2}}\right) \tag{47}
\end{equation*}
$$

As a result,

$$
\begin{equation*}
0 \leq\left\|F_{k}\right\|^{2} \leq\left|F_{k}^{T} d_{k}\right|\left(\frac{H^{2}}{h^{2}}\right) \longrightarrow 0 \tag{48}
\end{equation*}
$$

Hence,

$$
\begin{equation*}
\lim _{k \rightarrow \infty}\left\|F_{k}\right\|=0 \tag{49}
\end{equation*}
$$

## 4 Numerical experiments

The first part of this section provides numerical results to demonstrate the efficacy of the proposed method by comparing it with existing methods.

- IDFDD: Algorithm 1 proposed in [10].
- IDSL: Algorithm 1 proposed in [11].

The MDFDD method is used in the second part to solve the problem of Chandrasekhar's integral equation in radiative heat transfer. The computer codes used were written in MATLAB 9.4.0 (R2018a) and ran on a computer with a 1.80 GHz CPU processor and 8 GB RAM.

### 4.1 Experiment of some nonlinear systems of equations

In the experiments, we implemented the three algorithms using the same line search (23), with $\phi_{1}=\phi_{2}=10^{-4}, r=0.2$, and $\tau_{k}=\frac{1}{(k+1)^{2}}$. The iteration is set to stop for the three methods if $\left\|F_{k}\right\| \leq 10^{-5}$ or when the number of iterations overreaches 1000 , but there is no $x_{k}$ meeting the stopping criterion. The numerical effects of the three methods are shown in Tables 3-9, where "ITRN," "CTM(S)," and "IP" represent the total number of iterations, CPU time (in seconds), and initial points, respectively. In addition, $\|F k\|$ represents the residual value at the stopping point. The symbol "-" indicates failure due to a memory requirement or when some iterations exceed 1000. We tested the three methods on the current seven test problems, each with a different set of initial points and dimensions ( $n$ values). The experiment was carried out with the dimensions $100,1,000,2,000,10,000,50,000$, and 100,000 to demonstrate the comprehensive numerical experiments of the MDFDD, IDFDD, and IDSL methods. Table 2 contains the starting points for the test problems.

The experiments made use of the following test problems:
Problem 1 [8]
$F_{1}=x_{1}-e^{\cos \left(\frac{x_{1}+x_{2}}{n+1}\right)}$,

Table 2: Initial points used in test problems

| INITIAL POINTS (IP) | VALUES |
| :---: | :--- |
| IP1 | $\left(\frac{1}{2}, \frac{1}{2}, \ldots, \frac{1}{2}\right)^{T}$ |

$F_{i}=x_{i}-e^{\cos \left(\frac{x_{i-1}+x_{i}+x_{i+1}}{n+1}\right)}$,
$F_{n}=x_{n}-e^{\cos \left(\frac{x_{n-1}+x_{n}}{n+1}\right)}, \quad i=2,3, \ldots, n-1$.
Problem 2 [11]
$F_{i}(x)=x_{i}\left(1+x_{i} x_{n-2} x_{n-1} x_{n}\right)-2+\left(1-x_{i}^{2}\right), \quad i=1,2, \ldots, n$.
Problem 3 [24]
$F_{i}(x)=x_{i}-x_{i}\left(\sin x_{i}-\frac{11}{50}\right)+2, \quad i=1,2, \ldots, n$.
Problem 4 [10]
$F_{1}(x)=\left(x_{1}^{2}+x_{2}^{2}\right) x_{1}-1$,
$F_{i}(x)=\left(x_{i-1}^{2}+2 x_{i}^{2}+x_{i+1}^{2}\right) x_{i}-1$,
$F_{n}(x)=\left(x_{n-1}^{2}+x_{n}^{2}\right) x_{n}, \quad i=2,3, \ldots, n-1$.
Problem 5 [10]
$F_{i}(x)=2 x_{i}-\sin \left|x_{i}\right|, \quad i=1,2, \ldots, n$.
Problem 6 [11]
$F(x)=A x+b_{1}$,
where $A=\left(\begin{array}{ccccc}2 & -1 & & & \\ -1 & 2 & -1 & & \\ & \ddots & \ddots & \ddots & \\ & & \ddots & \ddots & -1 \\ & & & -1 & 2\end{array}\right)$, and $b_{1}=\left(e_{1}^{x}-1, \ldots, e_{n}^{x}-1\right)^{T}$.
Problem 7 [8]
$F(x)=B x+b_{2}$,
where $B=\left(\begin{array}{ccccc}2 & -1 & & & \\ 0 & 2 & -1 & \\ & \ddots & \ddots & \ddots & \\ & & \ddots & \ddots & -1 \\ & & & -1 & 2\end{array}\right)$, and $b_{2}=\left(\sin x_{1}-1, \ldots, \sin x_{n}-1\right)^{T}$.

From Tables $3-9$, we can observe that the three methods are trying to solve (1). However, the improvement and effectiveness of the proposed method are pretty straightforward. The tables indicated that modifying the IDFDD method in the proposed scheme is a good improvement. The MDFDD method remarkably outperforms the IDFDD and IDSL methods for nearly all the problems assessed since it has the least number of iterations, which are far below the number of iterations for the IDFDD and IDSL methods. Moreover, the proposed method has less CPU time than the IDFDD method. However, the MDFDD method has a higher CPU time than

Table 4: Numerical outcomes of MDFDD, IDFDD, and IDSL methods for problem 2

the IDSL method due to the computation of double direction in the MDFDD methods.

Figures 1-2 display the interpretation of the numerical results of each of the three methods using Dolan and Moré [5] performance profiles. We achieve this by plotting fraction $p(\tau)$ of problems for each method within $\tau$ of the smallest number of iterations and CPU time. As shown in Figures 1 and 2, the curves representing the MDFDD method remain above the IDFDD and IDSL methods in number iterations. Furthermore, it is above the curve representing the IDFDD method for the CPU time. Therefore, the proposed method outperforms the IDFDD and IDSL methods in fewer iterations and is thus the most efficient method. Finally, from the results in Tables 3-9, it is evident that the MDFDD method successfully solves problem (1).

Figure 1: Performance profile with respect to the number of iterations

### 4.2 Application in integral equations

Chandrasekhar and Breen [3] computed H-equation as the solution of the nonlinear integral equation that gives the complete nonlinear equations technique. The nonlinear integral equation arising in radiative heat transfer problem is given by

$$
\begin{equation*}
H(x)=1+c \frac{x}{2} H(x) \int_{0}^{1} \frac{H(y)}{x+y} d y \tag{50}
\end{equation*}
$$

Figure 2: Performance profile with respect to the CPU time (in second)
with parameter $c \in[0,1]$ and $H:[0,1] \rightarrow \mathbb{R}$ is an unknown function.
Equation (50) can be written as

$$
\begin{equation*}
H(x)=\left[1-\frac{c}{2} \int_{0}^{1} \frac{x H(y)}{x+y} d y\right]=1 \tag{51}
\end{equation*}
$$

By multiplying both sides of (51) with $\left(1-\frac{c}{2} \int_{0}^{1} \frac{x H(y)}{x+y} d y\right)^{-1}$, we have

$$
\begin{equation*}
F(H)(x)=H(x)-\left(1-\frac{c}{2} \int_{0}^{1} \frac{x H(y)}{x+y} d y\right)^{-1}=0 \tag{52}
\end{equation*}
$$

which is called the Chandrasekhar H-equation [23]. However, (52) can be discretized by using the midpoint quadrature formula

$$
\begin{equation*}
\int_{0}^{1} f(\mu) d \mu=h \sum_{j=1}^{n} f\left(\mu_{j}\right) \tag{53}
\end{equation*}
$$

for $\mu_{j}=(j-0.5) h, 0 \leq j \leq 1$, and $h=\frac{1}{n}$.
As a result, we have the following system of nonlinear equations:

$$
\begin{equation*}
F_{i}(x)=x_{i}-\left(1-\frac{c}{2 n} \sum_{j=1}^{n} \frac{\mu_{i} x_{j}}{\mu_{i}+\mu_{j}}\right)^{-1} i=1,2, \ldots, n, \quad j=1,2, \ldots, n \tag{54}
\end{equation*}
$$

which is known as the discretized Chandrasekhar H-equation that can be solved by using some iterative methods. If the initial point $x_{0}=(1,1,1, \ldots, 1)^{T}$, then the system in $(54)$ has a solution for all $c \in(0,1)$. However, the hardest part of the problem (54) is that the Jacobian is singular at $c=1$. Therefore as $c$ approaches 1 , the Jacobian approaches the singularity point. Since our method is derivative-free, then it has the advantage to solve problem (54) even when $c$ approaches 1 .

To highlight the performance of the MDFDD approach furthermore, we conduct some numerical experiments by comparing it with the classical NM, IDFDD method [10], and IDSL method [11]. The iteration is also set to terminate when $\left\|x_{k+1}-x_{k}\right\|+\left\|F_{k}\right\| \leq 10^{-5}$ or when the iterations exceed 1000, but no point of $x_{k}$ satisfying the stopping criterion. We have tried the three methods with the starting point of $x_{0}=(1,1,1, \ldots, 1)^{T}$. Furthermore, we use the dimensions ( $n$ values) 100 to 20,000 to show the performance of each of the three methods.

The numerical results of the methods used to solve Chandrasekhar Hequation with different values of parameter $c$, are shown in Table 10. The table clearly indicates that the proposed method outperformed the NM be-
cause the NM failed when the number of dimension increased. This is due to the fact that as $c$ approaches 1, the Jacobian approaches the singularity point. Moreover, the CPU time (in second) of the NM is higher than other methods because it solved the Jacobian matrix at each iteration. From Table 10 , we can also observe that the IDFDD method has totally failed because it has poor numerical performance, as we have made mentioned earlier in the introduction section of this article. Although, the IDSL method solved problem (54) completely, but it has more number of iterations than the MDFDD method. This shows that our method has effectively solved the discretized Chandrasekhar H-equation with the least number of iterations and CPU time.

## 5 Conclusion

In this article, numerical comparisons were made using a set of large-scale test problems. Furthermore, Tables 3-9 and Figures 1-2 showed that the presented method is practically quite efficient because it has fewer iterations than the IDFDD and IDSL methods. Furthermore, we have successfully used the proposed method to deal with experiments on the Chandrasekhar H-equation in radiative heat transfer. The experiments were carried out and reported in Table 10 with different $c$ values, demonstrating a better efficiency for the MDFDD method. The numerical results showed that the employed method solved the discretized integral equation with fewer iterations and CPU time than the NM, IDFDD, and IDSL methods. Future research includes applying the MDFDD scheme to solve the discretized three-dimensional nonlinear Poisson problem.
